Abstract. The Chilean *Puya* species (Puyoideae, Bromeliaceae) constitute an early diverging group within the genus and thus are key taxa for the understanding of the early evolution and biogeography of *Puya*. However, a modern taxonomic treatment including information from molecular phylogenetic studies is still lacking. Here, a taxonomic revision of the Chilean species of *Puya* is presented based on morphological, molecular, and biogeographic data. A re-evaluation of the widely applied concept of *P. berteroniana* led us to the conclusion that the type of *P. berteroniana* is of hybrid origin and is maintained as *Puya* × *berteroniana*. Our studies revealed that the name *P. berteroniana* has been widely misapplied to what in fact is the northern metapopulation of *P. alpestris*, which is here described as a new subspecies, *Puya alpestris* subsp. *zoellneri*, a member of subgenus *Puya*. A lectotype is designated for *Puya copiapina* and a neotype for *P. chilensis*. Altogether, six *Puya* species, two subspecies, four varieties and one hybrid taxon are recognized for the Chilean flora in this revision: *P. alpestris* subsp. *alpestris* and subsp. *zoellneri*; *P. boliviensis*; *P. chilensis*; *P. gilmartiniae*; *P. coerulea* var. *coerulea*, var. *intermedia*, var. *monteroana*, and var. *violacea*; *P. venusta*; and *P. × berteroniana*. A key is provided for their identification.

Key Words: Bromeliaceae, Chile, hybrid, *Puya*, *Puyopsis*.

The terrestrial bromeliad genus *Puya* Molina (Bromeliaceae) comprises 219 species (Luther, 2010) and occurs from Costa Rica to Chile and Argentina, from sea level to about 5000 m.a.s.l., and is principally confined to the Andes where the genus underwent a rapid radiation during the last 3.5 Ma (Smith & Downs, 1974; Givnish et al., 2011). Several species extend eastwards into the Guayana Shield and the Brazilian Amazon, and at the southern distribution limit of the genus, a

geographically highly isolated group is formed by the Chilean *Puya* species (Smith & Downs, 1974) occurring mainly in Central Chile which therefore represents a peculiar centre of diversity within the genus (Varadarajan, 1990; Zizka et al., 2009). The Chilean species also differ from their congeners by their unique ecology having successfully colonized not only semixerophytic to xeric Andean habitats but also extensive coastal habitats at low elevations.

The Chilean flora comprises approximately 5664 species of Angiosperms, of which 2727 are endemic (Marticorena, 1991). Bromeliaceae are represented in Chile with 23 species/20 endemics with the following genera: *Puya* (7 species/7 endemic; for the report of *P. alpestris* [Poepp.] Gay in Argentina [Gómez Romero & Grau, 2009] see comments below), *Tillandsia* L. (6/3), *Ochagavia* Phil. (4/4), *Greigia* Regel (4/4), *Fascicularia* Mez (1/1), and *Deuterocohnia* Mez (1/1) (Zizka et al., 2009). Although they represent only a small fraction of the overall diversity within the family (3248 spp.; Luther, 2010), recent molecular studies revealed their importance for our understanding of bromeliad evolution, in particular of the subfamily Puyoideae and its sister group Bromelioideae (Schulte et al., 2005, 2009, 2010; Horres et al., 2007; Sass & Specht, 2010).

For most of the Chilean bromeliads, updated revisions/treatments have been produced over the last few years, mainly in course of the studies for the "Flora of Chile" (*Ochagavia*: Zizka et al., 2002; *Fascicularia*: Zizka et al., 1999, the Chilean *Greigia*: Will & Zizka, 1999, *Deuterocohnia*: Schütz et al., 2009; Chilean *Tillandsia*: Zizka & Muñoz-Schick, 1993; Pinto, 2001, 2005; Pinto et al., 2006; Zizka et al., 2009). In contrast, a modern revision of the Chilean *Puya* species is lacking.

Puya was described by Ignacio Molina in 1782 in his "Saggio sulla storia naturale del Chili". Since then, our knowledge about the diversity of the genus has increased considerably, in particular over the last century (Mez, 1896: 44 spp.; Mez, 1935: 89 spp.; Smith & Downs, 1974: 168 spp.; Smith & Till, 1998: 190; Luther, 2010: 219 spp.). Traditionally, the genus was included in the subfamily Pitcairnioideae Harms based on ovary, fruit, and seed characters (Harms, 1930; Smith & Downs, 1974, Smith & Till, 1998). Based on a comprehensive cladistic study of morphological and anatomical characters, Varadarajan and Gilman (1988) placed *Puya* in the tribe Puyeae Mez together with *Abromeitiella* Mez, *Brewcaria* L. B. Sm., Steyermark & H. Rob., *Deuterocohnia*, *Dyckia* Schult. f., *Encholirium* Mart. ex Schult., and *Hechtia* Klotzsch. Smith and Till (1998) maintained this classification, but sank *Abromeitiella* in *Deuterocohnia*. Recent molecular studies demonstrated that the

genera formerly subsumed in Puyeae are not closely related and that *Puya* is not part of the Pitcairnioideae s.str., but instead constitutes a monophyletic lineage in sister group position to subfamily Bromelioideae (Horres et al., 2000; Givnish et al., 2004, 2007, 2011; Schulte et al., 2005). Hence, Givnish et al. (2007) erected the monogeneric subfamily Puyoideae.

In his first revision of the genus, Mez (1896) discerned three subgenera within *Puya* based on inflorescence characters: *Eupuya* (compound inflorescence, inflorescence branches with sterile apices), *Pitcairniopsis* Mez (compound inflorescence, fertile throughout), and *Pourretia* Mez (inflorescence unbranched). Smith and Looser (1935) described the subgenus *Chagualia* but Smith revised the subgeneric classification later on (Smith, 1964) sinking subgen. *Chagualia* and subgen. *Pourretia* into a more broadly defined subgenus *Pitcairniopsis*, thus recognizing only two subgenera for *Puya* based on the presence or absence of sterile terminal parts on the partial inflorescences. Based on nomenclatural considerations Smith then recombined *Puya* subgen. *Pitcairniopsis* to *Puya* subgen. *Puyopsis* (Baker) L.B. Sm., and subgen. *Eupuya* to subgen. *Puya* (Smith, 1970; Smith & Downs, 1974). By far the majority of the species in the genus belongs to subgen. *Puyopsis*, only nine species have been included in subgen. *Puya* (Smith & Downs, 1974; Hornung-Leoni & Sosa, 2008).

This subgeneric classification has recently been challenged by molecular phylogenetic studies that demonstrated the paraphyly of the two subgenera (Jabaly & Sytsma, 2010). In this study, two principal lineages within the genus were identified, the Core *Puya* (comprising the majority of the species), and sister to this the Chilean *Puya* which thus represent an early diverging group within the genus. The Core *Puya* clade comprises the majority of species traditionally placed in subgen. *Puyopsis*, whereas the Chilean *Puya* harbor the majority of the species placed in subgen. *Puya*. Of the seven Chilean *Puya* species five belong to subgen. *Puya* (*P. alpestris*, *P. berteroiana* Mez, *P. boliviensis* Baker, *P. chilensis* Molina, *P. gilmartiniae* G.S. Varad. & A.R. Flores) and two to subgen. *Puyopsis* (*P. coerulea* Lindl., *P. venusta* Phil.) (Smith & Downs, 1974). Besides the Chilean representatives of subgen. *Puya*,

three additional species were traditionally placed in the subgenus (*P. castellanosii* L.B. Sm.: Argentina; *P. weddelliana* Mez: Bolivia; and *P. raimondii* Harms: Peru, Bolivia; Smith & Downs, 1974; Hornung-Leoni & Sosa, 2008). In the light of the molecular data, the subgenus concept of *Puya* probably will have to be revised. Nevertheless, this is beyond the scope of our treatment here, therefore we keep the presently accepted concept of the two subgenera *Puya* and *Puyopsis*.

The most extensive revisions of this large genus are still those of Mez (1896, 1935) and Smith and Downs (1974). Other important contributions to our understanding of the systematics and evolution of the genus have been made by Varadarajan (1990), Varadarajan and Flores (1990), Hornung-Leoni and Sosa (2005, 2008) based on morphological studies, and Jabaly and Sytsma (2010) and Schulte et al. (2010) based on molecular phylogenetic analyses.

For the systematics and taxonomy of the Chilean species the important contribution of Smith and Looser (1935) is especially noteworthy. More recently, Gourlay (1952), Zizka (1992), Ravenna (2000), Echenique et al. (2003), and Muñoz-Schick (2003) have dealt briefly with some of the Chilean species, Trumper (1998) provided an extensive analysis of morphology and distribution of the Chilean species, and Zizka et al. (2009) on their distribution and conservation status.

Most of the Chilean *Puya* species are comparatively well circumscribed but morphological variability across the distribution of the species as well as occasional aberrant plants that may constitute hybrids can blur the morphological boundaries between taxa. The most problematic group within the Chilean *Puya* is the *Puya alpestris-P. berteroniana* species complex. As already described by Gourlay (1952), the fragmentary type specimen of *Puya berteroniana* Mez has been a matter of conflicting interpretations and species concepts. In particular, the type differs considerably from the plants Smith and Downs (1974) and other authors have applied the name to.

Recently, an AFLP study of the Chilean *Puya* species revealed that they represent three main genetic groups, with the purple flowered coerulea group (*P. coerulea*, *P. venusta*) and the

blue flowered alpestris group (*P. alpestris*, “*P. berteroniana*”) in sister group position to each other (Schulte et al., 2010), and the yellow flowered chilensis group (*P. boliviensis*, *P. chilensis*, *P. gilmartiniae*) as sister to both. Whereas *P. boliviensis*, *P. chilensis*, *P. coerulea*, *P. gilmartiniae*, and *P. venusta* were resolved as monophyletic clades in that study, this was not the case for the members of the *P. alpestris-P. berteroniana* species complex which again highlights the need of a revision of this group. Furthermore, the AFLP study confirmed the recent hybrid origin of morphologically intermediate individuals, and detected several additional hybrids. Hybrids were found in sympatric populations and were detected between the chilensis and the alpestris group as well as between the alpestris and the coerulea group (Schulte et al., 2010).

In the following we present an updated taxonomic revision of the Chilean *Puya* species based on our morphological, biogeographic, and genetic studies.

Material and methods

Collections of *Puya* from the herbaria B, BM, CONC, E, FR, FRP, G, GH, HAL, HBG, MO, NY, SGO, US, WU were studied. Additionally, species were studied during field trips in 2006–2007. Measurements of plant size were taken from living plants in their habitat, those of leaf length and width principally from herbarium specimens. Authors were abbreviated following Brummit and Powell (1992), descriptive terminology is based on Stearn (1992). The rank of the subspecies was used for taxa that show minor, but geographically structured discontinuities; if discontinuities are not geographically structured, then the rank of variety was used.

Taxonomic treatment

Puya Molina, Sag. Stor. Nat. Chili: 160, 351. 1782. Type: *Puya chilensis* Molina.

Renealmia Feuillée, J. Obs. Phys. Math. Bot. 3: 59, t. 39. 1725. Type: *Renealmia paniculata* L.

Pourretia Ruiz & Pav., Fl. Peruv. Prodr.: 46, t. 7. 1794. Type: *Pourretia lanuginosa* Ruiz & Pav.

Plants perennial, acaulescent or long caulescent, simple or branched, stout, often with a tall inflorescence. Leaves densely rosulate, coriaceous; sheath distinct, generally wide; blade narrowly triangular, the base not narrowed, mostly succulent and spinose-serrate. Inflorescence simple or paniculate. Flowers perfect, showy; sepals convolute, free, shorter than the petals, glabrous, tomentose, or lanate; petals free, with or without appendages, the blades tightly spiraled together after anthesis, distinct from claw; stamens generally shorter than the petals, the filament bases separate from each other after anthesis; ovary superior or slightly inferior, glabrous, style long, slender. Capsule loculicidal and often tardily septicidal as well; seeds appendaged, with a dorso-apical wing.

Distribution.—About 219 species distributed from Costa Rica to Chile and Argentina, principally Andean; seven species in Chile.

The genus *Puya* is easily distinguished from other closely related genera by the petal blades that are distinct from the claw and

spiraled together after anthesis, the appendaged seeds, the narrowly triangular leaf blades that are never contracted at base, and the superior to slightly inferior ovary.

Petal color is the most consistent character to distinguish species groups among Chilean *Puya*: petals are (greenish-) yellow in the *P. chilensis* group (*P. boliviensis*, *P. chilensis*, *P. gilmartiniae*), blue-green in the *P. alpestris*, and blue in the *P. coerulea* group (*P. coerulea*, *P. venusta*); in *P. × berteroniana* the petal color is unknown.

Some earlier works (e.g., Kunth, 1815: 296) cited *Achupalla* Kunth, originally published in Humboldt's (1810–13: 221, pl. 30: "Le premier plan du dessin présente un groupe de *Pourretia pyramidata*, plante voisine du *Pitcairnia*, connue dans les Cordillères sous le nom d'*achupallas*.") *Vues des Cordillères*, as a synonym of *Puya*. However, this name refers to a plant denominated *Pourretia pyramidata* Ruiz & Pav. and locally known by the Indians under the vernacular name of achupalla. Thus, achupalla was not intended as a scientific name.

Key to the Chilean species of *Puya*

1. Inflorescence compound, major portion of the branch apices sterile (subgen. *Puya*).
 2. Flowers metallic blue-green; leaf blades with contrasting sides (densely lepidote below).
 3. Flowering shoot 1.2–1.5(–2) m high; leaf-blades 15–25(–32) mm wide; inflorescence of up to 20(–40) branches, lax, the branches laxly few-flowered *Puya alpestris* ssp. *alpestris*
 3. Flowering shoot to (2–)2.5–5 m high; leaf-blades to 50 mm wide; inflorescence of (40–)50–80 (–100) branches, the branches densely many-flowered *Puya alpestris* ssp. *zoellneri*
 2. Flowers yellow to greenish; leaf blades concolourous.
 4. Flowers about 3 cm long, leaf-blades lepidote on both sides *Puya gilmartiniae*
 4. Flowers 4.5–7.3 cm long, leaf blades glabrous above.
 5. Inflorescence >0.8 m long, with 80–100 branches, dense *Puya chilensis*
 5. Inflorescence up to 0.5 m long, with few branches, lax *Puya boliviensis*
 1. Inflorescence compound, the branches fertile throughout or nearly so (subgen. *Puvopsis*).
 6. Flowers congested in apical part of inflorescence branches, inflorescence dense; floral bracts serrate *Puya venusta*
 6. Flowers not congested in apical part of inflorescence branches, inflorescence lax to ± dense; floral bracts entire.
 7. Inflorescence ± dense; plants very rare *Puya × berteroniana* (*Puya coerulea*).
 7. Inflorescence lax to ± dense.
 8. Floral bracts shorter than the pedicels, narrow *Puya coerulea* var. *violacea*
 8. Floral bracts about as long as or longer than the pedicels.
 9. Floral bracts exceeding the middle of the sepals; branches ± densely flowered *Puya coerulea* var. *coerulea*
 9. Floral bracts shorter than the middle of the sepals; branches laxly flowered.
 10. Inflorescence densely and persistently white-tomentose *Puya coerulea* var. *intermedia*
 10. Inflorescence glabrous by anthesis *Puya coerulea* var. *monteroana*

Puya subgen. *Puya* Molina, Sag. Stor. Nat. Chili: 160, 351. 1782. *Puya* subgen. *Eupuya* Mez, Monogr. Phaner. [DC.] 9: 472. 1896. nom. illeg. Type: *Puya chilensis* Molina.

Inflorescence compound, the lateral branches sterile toward apex (approximately upper third).

Puya alpestris (Poepp.) Gay, Fl. Chil. 6: 12. 1853.

Plants caulescent, in flower 1.2–5 m high, stems prostrate, branched. Leaves in a dense rosette 1–2 m in diameter; sheath 2.5–9.5×(0.9–)1.8–10 cm; blade 36–120×

0.35–4.6 cm, green above, yellowish-brown when dried, ± glabrous (to sparsely lepidote), densely whitish lepidote below; spines±curved, 2–10 mm long, brown, becoming further spaced apart from base to apex. Inflorescence (above the scape) 0.25–1 m long, with 15–100 racemose branches (partial inflorescences), these 6.5–32 cm long, in the lower third (to two thirds) fertile, the flowers densely spaced, sterile above with reduced bracts, these±hairy with stellate hairs, glabrescent when fruiting; scape 5.5–8 cm in diameter at base, densely hairy with stellate hairs when young, ± glabrescent; scape bracts caducous, broadly oblong, acuminate, 4.2–6×1.5–2 cm, with stellate trichomes, membranous, entire, conspicuously nerved; primary bracts ovate to oblong, 4–20×1.3–9.5 cm, dark brown when dried, membranous, densely lepidote, entire, ± serrate only toward apex; floral bracts elliptical, acuminate to mucronate, 1.2–2.7(–5)×0.4–2.2 cm, reaching up to about the middle of the sepals, whitish or brownish when dried, thinly membranous, ± hairy with stellate hairs, inconspicuously nerved, entire; pedicel 3–17×1–2 mm, green. Flowers 3.5–6 cm long; sepals oblong, apex rounded, sometimes with a mucro, 1.8–3.7×0.3–1 cm, green with whitish margin (fresh material), ± with stellate hairs, coriaceous, with membranous margin, nerved; petals elliptical, rounded to rarely acute, 3.6–5.7×1.3–2.5 cm, naked, metallic blue-green; stamens 6, filaments 2.3–3.5 cm long, anthers 5–9.3×1–1.5 mm, pollen orange; ovary 4×8 mm, style 3.1 cm long, stigmas 8 mm long. Fruit 1.5–2.2×1.3–1.8 cm; seeds 3–4×1.5–2.5 mm, ± triangular in outline, with membranous wing.

Distribution and ecology.—Endemic to Chile, occurring from Region IV to Region IX, between sea level and 2000 m. Its report from Argentina (Gómez Romero & Grau, 2009) remains doubtful since the cited plant was described as having violet petals, a state not known from *P. alpestris*. However, the cited collection could not be verified by us so far. *Puya alpestris* grows in stony, arid to semi-humid habitats.

Phenology.—Flowering between October and December.

Vernacular names.—Chagual.

Additional specimens examined (not assigned to subspecies): Chile. **Región IV:** Prov. Coquimbo, Dept. Ovalle, Fray Jorge, 15 Oct 1947, Sparre 3071 (SGO). **Región V:** Cuesta El Melón, subida Cuesta Alicahue, 13 Nov 1993, Muñoz Schick 3334 (SGO). **Región Metropolitana:** Filo del cerro entre cerro El Toro y cerro El Tollo, 5 Mar 2000, Arroyo & Humaña 201498 (SGO); Caleu, desde Carabineros hacia el Norte, 29 Nov 1993, Muñoz Schick 3349 (SGO). **Región VII:** Km 94 a Laguna del Maule, 20 Jan 2003, Muñoz Schick 4342 (SGO). **Región IX:** Primeros km subida a Parque Nacional Nahuelbuta, 18 Jan 2003, Muñoz Schick 4317 (SGO); Cautín, Near La Paz, Oct 1885, Rusby 2850 (NY, US).

***Puya alpestris* (Poepp.) Gay ssp. *alpestris*, Fl. Chil. 6: 12. 1853. *Pouretia alpestris* Poepp., Fragm. Syn. Pl.: 8. 1833. Type: Chile, Biobío: in der Nähe von Antuco, Cuesta del Prado, Feb 1829, E. F. Poeppig 93 (holotype: W, destroyed; lectotype, designated by Smith & Downs, 1974: BM; isotypes: B, G, HAL). (Fig. 1)**

Puya whytei Hook.f., Curtis's Bot. Mag. 94: t. 5732. 1868. Type: Chile, s.loc., 1864, M. Whyte 171/1 (holotype: K).

Puya pumila Ravenna, Onira 4(15): 57. 2000. Type: Chile. Región IX: In decliviis secus fluminem Bío-Bío, inter Santa Juana et Tanaollín, Dec 1999, Ravenna 3903 (holotype: Herb. Ravenna n.v.; isotypes: BA n.v., CONC n.v., SGO n.v.; see notes below).

“*Pitcairnia coerulea*” auct. non Benth.: Baker pro parte (not the *Puya coerulea* Lindl. element), Handb. Bromel.: 121. 1889 (see notes under *Puya coerulea* var. *coerulea*).

Plants in flower 1.2–2.5 m high. Leaves in comparatively low number; sheath 2.5–4.5 (–9)×0.9–5.3(–9) cm; blade 36–65(–98)×0.35–2.5(–3.2) cm, spines 2–8 mm long. Inflorescence (above the scape) 0.25–0.72 m long, with 15–20(–40) lateral branches, lower third to lower half of lateral braches fertile, the flowers±laxly disposed, rhachis glabrous to densely lepidote; primary bracts 4–11×1.3–4.5 cm; floral bracts whitish when dry, thin-membranous; pedicel 3–15×1–2 mm.

Distribution and ecology.—Endemic to Chile; distributed from Central Chile, Region VII (approx. 50 km E of Linares, Paso Pehuenche, 35°42'S) to Region IX (E of Temuco, Lonquimay, 38°27'S); from sea level to 2000 m. Abundant in Regions VIII and IX

As noted by Weber (1984: 576) the collection number of the type is *Poeppig* 93, not 891 (or Diar. 891). The latter refers to the page of his diary.

The type of *Puya pumila* Ravenna could not be traced in the public herbaria (BA, CONC, SGO) indicated in the protologue. We therefore assume that all the material is still held at Ravenna's private herbarium. Nevertheless, the description clearly shows its synonymy with *Puya alpestris* subsp. *alpestris*.

Puya alpestris has been reported to contain pale pink to red-wine-like or blue nectar (Hansen et al., 2007).

Puya alpestris subsp. **zoellneri** (Mez) Zizka, J.V. Schneid. & Novoa, subsp. nov. Type: Chile. Region V: Viña del Mar, Camino El Olivar, 70°65'015"W, 33°43'773"S, 300 m a.s.l., 10 Dec 2006, G. Zizka 8004 (holotype: FR-0028991). (Figs. 1, 2)

Bromeliad Soc. 39(1): 6. 1989; Zizka, Palmengarten 19: 98. 1992.

Plants in flower (2–)2.5–4.5 m high. Leaves numerous, in a dense rosette; sheath 3.8–9.5 × 4–10 cm; blade 54.5–120 × 1.4–4.6 cm, with spines 8–10 mm long. Inflorescence (fertile part) c. 1 m long, with (40–)50–80(–100) lateral branches, these at least 20 cm long, the lower third to half of lateral braches fertile, the flowers ± dense, rachis ± densely hairy with stellate trichomes; primary bracts 8–20 × 2.4–9.5 cm; floral bracts brownish when dry, ± membranous; pedicel 5–17 × 1–2 mm.

Distribution and ecology.—Endemic to Chile; distributed from North and Central Chile, Region IV (ca. 75 km N of La Serena, Incahuasi, 29°15'S) to Region VII (ca. 80 km E of Cúrico, Termas del Flaco, 34°56'S); from sea level to 2200 m. Abundant in Region V and Región Metropolitana (between Valparaíso and Santiago, ca. 33°–34° S). Grows in stony, arid habitats.

Phenology.—Flowering between October and December.

Conservation.—Least concern (Zizka et al., 2009; therein discussed under *P. berteroiana* sensu Smith & Downs, 1974).

Etymology.—This species is named in honor of the german-born botanist and specialist of the Chilean flora Otto Zöllner (1909–2007).

plant: grown near Hutchin, England, 12 Nov 1951, Gourlay s.n. (US-2048519).

As first noted by Smith and Looser (1935), *Puya alpestris* is a highly variable species showing two different forms across a north-south gradient, a large one with dense spikes and a northern distribution and a small one with laxly disposed lateral inflorescences and a southern distribution. Gourlay (1952) discussed this variation in more detail and noted that *Puya whytei* corresponds to the small form originally described as *P. alpestris* by Poeppig. Following a letter from L. B. Smith, Gourlay agreed on using the name *P. berteroniana* for the large form, although he was aware of the problematic concept of that species (see notes under *P. × berteroniana*). Smith and Downs (1974) continued to use the name *P. berteroniana* for the larger northern form. However, the original description of *P. berteroniana*, based on the fragmentary specimen *Bertero 115*, does not correspond with the plants of the northern form due to their different inflorescences. Therefore, we describe the new subspecies for all plants corresponding to the northern form, while *P. berteroniana* is considered a very rarely collected (and presumably rare) species of putative hybrid origin (see below).

Puya alpestris subsp. *zoellneri* differs from subsp. *alpestris* in having leaf blades to 4.6 cm broad (0.35–2.5[–3.2] cm in subsp. *alpestris*) and inflorescences with at least 40 lateral branches (up to 20 in subsp. *alpestris*). Additionally, the flowering plants are (2–)2.5–4.5 m tall (to 2.5 m in subsp. *alpestris*).

Puya boliviensis Baker, Handb. Bromel.: 126. 1889. Type: Chile, Region II: Antofagasta, Cobija, Jul 1836, C. Gaudichaud s.n. (holotype: P; isotypes: B, F, US).

Puya copiapina Phil., Anales Univ. Chile 91: 613. 1895. Type: Chile, Region III (Atacama): Morro de Caldera, 1888, W. Geisse s.n. (lectotype, here designated: SGO 46420).

Plants ± caulescent, in flower 1–2 m high, stems ± prostrate. Leaves numerous, in a dense rosette, ± erect; sheath (1.2–)2–5×1.6–6.5 cm, ± ovate, brown, margin spinose apically, entire towards base, below lepidote, glabrescent towards base, above glabrous, shining; blade 16–45.3(>100)×(1–)2.3–3.5

(–6) cm, ± green, sparsely lepidote and glabrescent above, lepidote to glabrous below (scales only persistent in the furrows), spines ± hook-shaped, 6–8(–10) mm long, brown, approx. 2 cm apart. Inflorescence (above the scape) c. 50 cm long, usually lepidote, with c. 20 racemose branches (partial inflorescences), these 13–21 cm long, axis of partial inflorescence densely covered with stellate trichomes, the lower half fertile, the flowers laxly spaced, sterile above with reduced bracts, the sterile bracts similar to the floral bracts but smaller; scape bracts narrowly triangular (lower ones) to broadly ovate (upper ones), acuminate, 9.2×2.5 cm, brown, with stellate trichomes, membranous, nerved, margin ± spinose, becoming entire towards flowering part; primary bracts ovate, 1.9–2.5×4.2–5.7 cm, brown when dried, ± membranous, lepidote, inconspicuously nerved, entire; floral bracts elliptical to ovate, acuminate, rarely rounded with a mucro, 2.1–3.5×0.6–1.8 cm, reaching up to about the middle of the sepals, rarely up to about as long as the sepals, dark brown, membranous, ± lepidote with stellate hairs, conspicuously nerved, entire; pedicel 8–15×1–2 mm. Flowers 4.5–6.1 cm long; sepals lanceolate, apex rounded, sometimes with mucro or acute, 1.8–3.5×0.4–0.7 cm, light brown, ± hairy with stellate hairs, coriaceous, longitudinally striate, margin entire, nerved; petals elliptical to spatulate, rounded with inconspicuous mucro, 4.5–5×1.9–2.1 cm, yellow to greenish, naked, with green spot at base; stamens 6, filaments 2.4–3 cm long, anthers 7.5–11×1–1.5 mm, pollen yellow to orange; ovary 8.5×2 cm, style 2–2.8 cm long, stigmas 6 mm long. Fruit 1.5–2.4×1.3–2 cm; seeds 3–4×3 mm, broadly triangular in outline, with membranous wing.

Distribution and Ecology.—Endemic to northern Chile; distributed in Region II (Antofagasta, 22°30'–26° S), up to about 670 m. Grows in rocky, arid areas of the coastal cordillera.

Phenology.—Flowering between November and February.

Conservation.—Endangered (Zizka et al., 2009).

Vernacular name.—None reported.

Additional specimens examined. CHILE. Región II: Tocopilla, Cobija, *Gaudichaud* s.n. (US-2144942); Tocopilla, Cobija, Jul 1836, *Gaudichaud* s.n. Puya boliviensis is morphologically closest to *P. chilensis* and *P. gilmartiniae*. It differs from the first in its shorter inflorescence with about 20 lateral branches (80 or more in *P. chilensis*), and from the latter by the larger flowers (4.5–6.1 cm long compared to about 3 cm in *P. gilmartiniae*) and glabrous adaxial leaf surface (lepidote in *P. gilmartiniae*). *Puya boliviensis* is also geographically the most isolated of all Chilean *Puya* species.

Muñoz (1960) identified two specimens collected by Geisse s.n. as the types of *Puya copiapina* Phil., SGO 46420 and SGO 71679, among which we chose the first as the lectotype.

Puya chilensis Molina, Sag. Stor. Nat. Chili: 160, 351. 1782. Type: Description (herbarium and types of Molina unknown [Stafleu & Cowan, 1981]); Chile. Región VIII: Prov. Puya gigantea Phil., Linnaea 33: 246. 1864; *Puya chilensis* "var. *P. gigantea*" (Phil.) Baker, Handb. Bromel.: 127. 1889, comb. illeg.; *Puya chilensis* var. *gigantea* Baker ex Mez, Monogr. Phaner. [DC.] 9: 473. 1896. Type: Chile. Aconcagua, Los Molles, Nov 1862, C. L. Landbeck s.n. (lectotype, designated by Muñoz, 1960: SGO 46417).

Puya quillotana Weber, Feddes Repert. 95(9–10): 577. 1984. Type: Chile. Prope Quillota, C. Bertero 1261 (holotype: HAL; isotypes: KIEL, WU [photo]).

Plants caulescent, in flower up to 4(–5) m high, stems prostrate, branched, 15–20 cm in diameter. Leaves numerous, in a dense rosette approx. 1 m high; sheath 7–10×4.4–10 cm, ovate, dark brown, margin apically spinose, entire toward base, above glabrous, below densely lepidote, glabrescent towards base; blade 55–107×2.3–5.7 cm, yellowish-green when dried, soon glabrous on both sides, the scales usually persistent in the longitudinal furrows of the leaf, spines 7–15 mm long, brown, several cm apart, becoming more distant from base to apex. Inflorescence ≥1 m high, triangular in outline; scape bracts ovate, acuminate, 9.8×2.8 cm, ± lepidote, membranous, nerved, entire or spinose-serrate towards apex; with 80–100 racemose branches (partial inflorescences), these 21–30 cm long, axis of partial inflorescence densely covered with stellate trichomes, glabrescent after anthesis, in lower third to half fertile, the flowers densely spaced, sterile above with reduced bracts, these ± hairy with stellate hairs, glabrescent at fruiting time, sterile bracts similar to floral bracts but smaller, primary bracts ovate to broadly ovate, 6.5–15.5×2.5–6.8 cm, dark brown when dried, membranous, densely lepidote, ± prominently nerved, margin basally entire, ± serrate towards apex; floral bracts variable, elliptical to lanceolate or ovate, acuminate, (1.5)–2.5–4.5×0.7–2.1 cm, often exceeding the sepals, at least reaching up to about the middle of the sepals, dark brown, thin membranous, ± hairy with stellate hairs, inconspicuously nerved, entire; pedicel 7–15×1.5–3 mm. Flowers 5–7.3 cm long; sepals narrowly elliptical to lanceolate, apex rounded, sometimes with a mucro or acute, 2.1–4×0.3–0.9 cm, ± hairy with stellate hairs, coriaceous, entire, nerved; petals narrowly elliptical, rounded to rarely acute, 4–7×0.8–2.1 cm, yellow to green, naked; stamens 6, filaments 3–4.5 cm long, anthers 7–15×1.5 mm, pollen yellow; ovary 7–11×3–5 mm, style 3.4–4.5 cm long, stigmas 7–10 mm long. Fruit 1.7–2.7×1–2.5 cm; seeds 2.5–5×2–3 mm, ± triangular in outline, with membranous wing.

Distribution and ecology.—Endemic to Chile; distributed from Central Chile, Region IV (La Serena, 30°S) to Region VIII (S of Concepción-Estación El Fuente, 37°11'S), abundant in Region IV and V (La Serena, 30°S – Valparaíso, 33°S); between sea level and 900 m. Grows in stony terrain close to the coast and in interior mountains.

Phenology.—Flowering from August to November.

Conservation.—Least concern (Zizka et al., 2009).

Vernacular names.—Cardón, Chagual, Puya.

Recent molecular studies (Schulte et al., 2010) confirmed the view that *Puya chilensis* is most closely related to *P. boliviensis* and *P. gilmartiniae*. All three species share the yellow to greenish flowers, a characteristic not found in the other Chilean *Puya* species.

A type specimen could not be traced for *P. chilensis* (the herbarium and types of Molina are unknown [Stafleu & Cowan, 1981]) and the protologue provides only a short diagnosis. Therefore, a neotype has been designated here.

Philippi cited a collection of Landbeck s.n. from Los Molles, Prov. Aconcagua as the type of *Puya gigantea* Phil. Among the collections held at SGO, Muñoz (1960) identified the specimen SGO 46417 as the type, which we here consider an indirect lectotypification.

Puya quillotana was described by Weber (1984), but has been shown to be conspecific with *P. chilensis* by Trumpler (1998) and Hornung-Leoni & Sosa (2008).

Puya gilmartiniae G.S. Varad. & A.R. Flores, J. Bromeliad Soc. 40(4): 161. 1990. Type: Chile, Region IV (Coquimbo): Elqui, about 60 km N of La Serena, on the way to Punta Totoralillo, near El Olivo, Isla Tilgo, 22 May 1987, G.

S. Varadarajan et al. 1481 (holotype: GH; isotypes: MO, WS n.v.).

Plants caulescent, in flower 1.5–2 m high, stems prostrate, branched, 30–50 cm long. Leaves 15–20 in a dense rosette, arching; sheath 2–5 × 3.7–6 cm; blade 26–60 × 1.5–2.5 cm, lepidote above and beneath, more densely towards the margin and near the spines, the spines 7–10 mm long, 1.2–2 cm apart. Inflorescence (above the scape) 37–60 cm long, with up to 24 racemose branches (partial inflorescences), these 15.5–38 cm long, the axis woolly, glabrescent after anthesis, the lower third fertile, the flowers densely spaced, sterile above with reduced bracts, these similar to the floral bracts but smaller; scape bracts narrowly triangular to broadly lanceolate, acuminate, membranous, nerved, entire; primary bracts ovate to lanceolate, 13 × 3.5 cm, brown when dried, membranous, ± veined, margin entire; floral bracts elliptical to ovate, acuminate, 2.4 × 1.2 cm, equalling or exceeding the sepals, brown, membranous, inconspicuously nerved, entire; pedicel 7–10 × 2 mm. Flowers 3 cm long; sepals elliptical to lanceolate, apex rounded, ± mucronate, 1.5–2.3 × 0.4–0.6 cm, subcoriaceous, nerved, entire; petals elliptical, 2.6–3 × 0.9 cm, yellow, naked; stamens and ovary not seen. Fruit 2.3–3.5 × 2–2.3 cm; seeds 2–3.3 × 3 mm, broadly triangular in outline, with a membranous wing.

Distribution and ecology.—Endemic to central Chile, known only from Region IV (29°16'–29°39'S). Grows in coastal scrub vegetation between 50 and 520 m.

Conservation.—Critically endangered (Zizka et al., 2009).

Additional specimens examined. CHILE. Región IV: Elqui, La Serena: Puente Juan Soldado, just before Cuesta Buenos Aires, 30 Nov 2004, Baxter et al. DCI 1753 (E); Chungungo, Straße von Chungungo zur Mine El Tolfo, ca. 5 km von Chungungo entfernt, 22 Dec 2006, Zizka 8128 (CONC, FR).

This species is morphologically most similar to *P. boliviensis* and *P. chilensis* from which it differs by its smaller flowers. Varadarajan and Flores (1990) suggested that *P. gilmartiniae* might be a hybrid derived from a crossing between *P.*

boliviensis and *P. chilensis* because some features appear to be intermediate between the putative parental species and because the rather narrowly distributed *P. gilmartiniae* occurs at the northern limit of *P. chilensis* and south of the area of *P. boliviensis*. The actual distribution area of the latter lies about 200–300 km north of the area of the other two species but the areas of all three species might have been confluent during former more humid periods. Interestingly, molecular studies (Schulte et al., 2010) support the idea of a hybrid origin involving the mentioned species.

Puya gilmartinii was named in honor of Amy Jean Gilmartin and therefore is to be changed to *P. gilmartiniae* according to ICBN (McNeill et al., 2007), art. 60.11., ex. 30.

 Lectotype, designated by L.B. Smith, 1970: *Pitcairnia brachystachya* Baker (= *Puya brachystachya* [Baker] Mez).

Puya subgen. *Pitcairniopsis* Mez, Monogr. Phaner. [DC.] 9: 475. 1896. Type: *Pourretia floccosa* Linden.

Puya subgen. *Pourretia* Mez, Monogr. Phaner. [DC.] 9: 489. 1896, comb. illeg. Type: *Pourretia lanuginosa* Ruiz & Pav.

Puya subgen. *Chagualia* L.B. Sm. & Looser, Revista Univ. (Santiago) 20: 243. 1935. Type: *Puya coerulea* Lindl.

Inflorescence and its branches fertile throughout.

Puya × berteroniana Mez, Monogr. Phaner. [DC.] 9: 477. 1896. Type: Chile, Region V: Quillota, La Quinta, 1818, C. L. G. Bertero 115 (holotype: P; isotypes: B, G).

Habit, leaves, and inflorescence unknown. Partial inflorescences basally for 1.6–3.2 cm sterile, broadly triangular in outline, 19.5–28 cm long; rachis densely covered with stellate trichomes, flowers ± dense, fertile throughout, bracts reduced in size towards apex; primary bracts ovate, 8.5–12.5 × ca. 3.5 cm, brown, lepidote, membranous,

nerved, serrate; floral bracts elliptical to rarely ovate, acute to acuminate, 2–5 × 0.7–1.4 cm, exceeding the sepals, reddish below, lepidote, ± membranous, nerved, entire; pedicel 5–12 × 1.5–2.5 mm. Flowers 2.7–5.2 cm long; sepals rounded and rarely mucronate to acuminate, 1.8–4 × 0.4–0.6 cm, coriaceous, prominently nerved, entire; petals 4.5 cm long; filaments 3 cm long, pollen yellow; ovary 6 × 3 mm, style and stigma not seen. Fruit and seeds not known.

Distribution and ecology.—Only known from the type.

Puya berteroniana has been the most problematic species of the genus in Chile (Smith & Looser, 1935; Gourlay, 1952) for its identity and taxonomic rank have remained unclear up to now. Mez (1896) based the species on a fragmentary specimen collected by Carlos Bertero (no. 115) in the region of Valparaíso, kept at Paris (P). The specimen is similar to *P. alpestris* but lacks the extensive terminal sterile parts of the partial inflorescences (although few presumably sterile floral bracts are found densely spaced at the terminal end). Consequently, Mez placed his new species in the subgenus *Pitcairniopsis* Mez [= *Puya* subgen. *Puyopsis* (Baker) L.B. Sm.], characterized by partial inflorescences without sterile terminal parts. No similar plants were reported until recently and Smith and Looser (1935), based on personal communication from Prof. Benoist who had been able to study the type specimen at P and reported sterile bracts for the tip of the branches, declared *P. berteroniana* to be synonymous with *P. alpestris*. Later, Smith and Downs (1974) revised the material and kept both as separate species in *Puya* subgenus *Puya*. They applied the name *P. berteroniana* for plants with bluish flowers very similar to *P. alpestris*, but larger in all parts, with more branches per inflorescence and more northerly distributed. This taxonomic concept was commonly applied until now, although the differences between the type specimen of *P. berteroniana* and the plants usually named so, remained (a problem already recognized by Gourlay [1952]). Moreover, the species rank of the two groups (*P. alpestris* and *P. berteroniana* sensu Smith and Downs 1974) has never been thoroughly assessed. The fact that the northern and the southern taxa are obviously very similar

and the plants apparently become gradually taller from south to north cast doubt on their status as distinct species.

As far as *Puya berteroniana* Mez is concerned, our analysis of the inflorescence confirmed Mez' view that the terminal sterile parts characteristic for subgenus *Puya* are not found on the plant documented by the holotype (P) and the isotypes (B, G) of this taxon. As already argued by Smith and Looser (1935), no plants similar to the type have been collected, which makes it highly probable to regard *P. berteroniana* Mez as i) a very rare, by now extinct species, ii) based on a teratological specimen or iii) a product of hybridisation.

In 2006, a plant could be observed at Pichidangui (*Zizka* 8119 [CONC, FR]) that appeared to be intermediate between *P. alpestris* subsp. *zoellneri* and *P. venusta*, both occurring sympatrically in the area. The Pichidangui plant resembled the type specimen of *P. berteroniana* in having an inflorescence similar to *P. alpestris* but lacking the sterile terminal parts; the leaves also resembled those of *P. alpestris*. Interestingly, the further investigation of this specimen revealed it to be genetically intermediate between *P. alpestris* and the *P. coerulea* group (Schulte et al., 2010). Nonetheless, for *P. coerulea* does not occur in the area of Pichidangui, considering it as one of the parental species is not yet convincing. Among the material studied, there is also a specimen (*Flores* s.n. [SGO 119847]) from Playa Las Tacas in the Coquimbo region that is similar to *Zizka* 8119 and *P. × berteroniana*. Since the extent of hybrid formation and the putative parental species are still unclear, we refrain from assigning them to a taxon. However, *Puya berteroniana* Mez is here regarded to be a very rare taxon of hybrid origin. Up to now, *Puya* hybrids have been only reported by Luther (2010) who listed two species of hybrid origin (*P. × loxensis* Manzanares & W. Till, *P. × pichinchae* Mez & Sodiro), but no hybrids between representatives of different subgenera have been recorded up to now. However, a hybrid between the genera *Puya* and *Deuterocohnia*, *× Pucohnia* G.H. Anderson ex D.A. Beadle, was published by Beadle (1991).

Among the type collections (*Bertero* 115) the specimen labels bear heterogeneous in-

formation concerning collection sites and dates. They were either collected in La Quinta in 1818 or close to Rancagua in 1824. As pointed out by Smith and Looser (1935), La Quinta lies west of Requínoa, close to Coínco, in the province of Colchagua, and is a locality quite far away from Quillota; the Quinta collection corresponds with the one collected close to Rancagua. Whether one of the collection sites is erroneous – as suspected by Smith and Looser (1935) – or whether *Bertero* 115 is a heterogeneous collection remains unclear.

There has been some confusion about the correct epithet of *P. berteroniana*. Stuessy and Marticorena (1990) proposed to change the original name to *P. berteroana*. However, *P. berteroniana* is the correct spelling according to the ICBN (McNeill et al., 2007), art. 60.6., ex. 14.

***Puya coerulea* Lindl.**

Plants in flower 1–2.7 m high, caulescent, stems prostrate or erect, branched, 3 cm in diameter, covered by the old leaf bases. Leaves numerous, ± 25, in a dense rosette 0.75–1 m in diameter; sheath 2–12 × 1.5–13 cm; blade 11–62 × 0.4–5 cm, whitish to glaucous, densely lepidote, spinose, the spines ± hook-shaped, 2–5 mm long, reddish to brown, 0.3–1.5 cm apart at base, 3.5 cm apart towards apex. Scape up to 1 m high, 0.9–2 cm in diameter, greyish-green to reddish, inconspicuously longitudinally striate, woolly when young, becoming glabrous; scape bracts triangular or ovate, acuminate; 3.9–9.7 × 0.8–1.3 cm, ± lepidote, inconspicuously nerved, serrate. Inflorescence (above the scape) 0.5–1.1 m long, with racemose partial inflorescences, these 5–17.5 cm long (terminal inflorescence 19.5–28.5 cm); axis of partial inflorescence densely woolly-lepidote, glabrescent; primary bracts triangular to ovate, 1.4–10 × 0.4–2.5 cm, shorter than the lateral branches, ± lepidote, chartaceous to membranous, inconspicuously nerved, serrate; floral bracts highly variable, elliptical to ovate, acute to acuminate, 0.3–4.4 × 0.1–2 cm, thinly membranous, inconspicuously nerved, entire or serrate; pedicel 3–24 × 1.5–2.5 mm. Flowers 3.2–6 cm long; sepals triangular to lanceolate, apex rounded, sometimes with a mucro or rarely acuminate, 1.2–3 × 0.2–0.9 cm, green

(fresh material), membranous to coriaceous, thinly membranous at margin, entire or inconspicuously serrate; petals elliptical, rounded, $2.8\text{--}5.2 \times 1.3\text{--}2.5$ cm, blue to blue-violet, with 2 appendages at base; stamens 6, filaments 3.4–4.7 cm long, anthers $4\text{--}8 \times 1\text{--}1.5$ mm, pollen yellow to orange; ovary pyramidal, $7\text{--}8 \times 4$ mm, style 2.7–3 cm long, stigmas 3-parted, 3–6 mm long. Fruit $1\text{--}1.8 \times 1\text{--}1.5$ cm; seeds $2\text{--}3 \times 1\text{--}2.5$ mm, narrowly triangular in outline, flattened, with membranous wing.

Distribution and ecology.—Endemic to Chile; distributed from Region IV to Region IX ($30^{\circ}05'\text{--}36^{\circ}38'S$), between (20–)100 and 2200 m. Grows in stony, arid areas.

Phenology.—Flowering from October to March.

Vernacular names.—Chagual chico, Chagualillo, Pipolle.

Puya coerulea is a morphologically highly variable species that was subdivided into four varieties by Smith and Looser (Smith, 1970), principally based on differences in relative lengths of floral bracts, pedicels, and sepals. Here, we adopt this widely accepted classification, although numerous morphologically intermediate plants exist, blurring the boundaries between the varieties. *Puya coerulea* var. *coerulea* appears to be the only group that is confined to the Chilean Coastal Cordillera, while the others are found on the western slopes of the Andes, the Central Valley and the coastal border. The varieties *violacea* and *intermedia* occur sympatrically as do var. *monteroana* and var. *intermedia*.

Interestingly, a molecular study revealed two subgroups within *P. coerulea* that apparently reflect geographical differences, one being a moderately supported *Puya coerulea* var. *coerulea*, the other one uniting the remaining three varieties, with the exception of one accession of var. *intermedia* (Schulte et al., 2010). The last varieties seem to be especially subject to gene flow, explaining their poorly defined taxonomic boundaries.

P. coerulea Lindl. var. *coerulea*, Edwards's Bot. Reg. 26: pl. 11. 1840. Type: Typified by original description and figure. (Fig. 1)

Pourretia coerulea Miers, Trav. Chile 2: 531. 1826, nom. nud.

Pitcairnia coerulea (Lindl.) Benth., Gen. Pl. [Bentham & Hooker f.] 3(2): 666. 1883 (see notes).

“*Pitcairnia coerulea*” auct. non Benth.: Baker pro parte (not the *Puya alpestris* element), Handb. Bromel.: 121. 1889 (see notes).

“*Puya violacea*” auct. non Mez: Watson, Curtis's Bot. Mag. 134: pl. 8194. 1908.

Plants in flower to 2.5 m high. Leaf sheath $4.5\text{--}12 \times 5.3\text{--}13$ cm; blade $36\text{--}62 \times 1.5\text{--}3.5$ (–5) cm. Inflorescence woolly, the partial inflorescences fertile throughout, flowers densely spaced; primary bracts $4.7\text{--}10 \times 1\text{--}3$ cm; floral bracts $1\text{--}4.4 \times 0.4\text{--}1.5$ cm, membranous, reaching about the lower third of the sepals, rarely about as long as these; pedicel $3\text{--}15 \times 1.5\text{--}2.5$ mm.

Distribution and ecology.—Endemic to Chile; distributed from the Region IV (Playa Las Tacas, $30^{\circ}05'S$) to Region VI (Cachapoal, $33^{\circ}55'S$), between (20–)500 and 2000 m; confined to the Coastal Cordillera. Grows in stony, semiarid areas.

Phenology.—Flowering between October and February.

Conservation.—Near threatened (Zizka et al., 2009).

Vernacular names.—Chagual, Chagualillo.

Additional specimens examined. Chile. Lindley referred the name *Puya coerulea* to Miers (1826) who published the name *Pourretia coerulea* without a description. The plant used for Lindley's description was the same as used by Miers (Lindley, 1840). Smith and Looser (1935) searched the type collections of Lindley held at CGE but did not find a specimen corresponding to *Puya coerulea*. Therefore, they concluded that Lindley had not preserved a herbarium specimen made from the cultivated plant used for his original description and drawing. Since this description is sufficiently detailed to recognize unambiguously the species, we refrained from designating an epitype.

In his publication of *Pitcairnia coerulea* Benthham (1883: 666) referred to Lindley's *Puya coerulea*: "P. caerulea (*Puya caerulea*, Miers in Lindl. Bot. Reg. 1840, t. 11)." Therefore, he made a new combination. Baker's (1889) description of *Pitcairnia coerulea* contained two elements, one of them corresponding to *Puya coerulea* Lindl., the other one to *Puya alpestris* Poepp. (including *P. whytei* Hook.f.).

Puya coerulea var. intermedia (L.B. Sm. & Looser) L.B. Sm. & Looser, Phytologia 19: 287. 1970. *Puya violacea* var. *intermedia* L.B. Sm. & Looser, Revista Univ. (Santiago) 20: 252. 1935. Type: Chile, Colchagua, Baños de Cauquenes, 3–4 Apr 1931, G. Looser 2015 (holotype: GH).

Puya paniculata Phil., Linnaea 33: 247. 1864. *Pitcairnia philippii* Baker, Handb. Bromel.: 122. 1889, nom. nov., non *Pitcairnia paniculata* Ruiz

& Pav. Type: Chile, Colchagua, *R. A. Philippi s.n.* (lectotype, designated by Smith & Looser, 1935; B n.v.; isotype: BM).

Puya glabrata Phil. ex Baker, Handb. Bromel.: 122. 1889; nom. nud.

Plants in flower up to 2.3 m high. Leaf sheath 2.6–8.5×3.4–5.7 cm; blade 45–47×1–1.9 cm. Partial inflorescence basally sterile for 3–5 cm, flowers loosely spaced, whitish woolly, glabrescent; floral bracts 1.2–1.8(–2.7)×0.3–0.6 cm, thinly membranous, reaching the base or rarely up to the upper third of the sepals; pedicel 5–15×1.5–2 mm.

Distribution and ecology.—Endemic to Chile; distributed from Region V (Quillota, 32°59'S) to Region VII (Constitución, 35°20' S), between sea level and 1100 m. Grows on stony hills.

Conservation.—Near threatened (Zizka et al., 2009).

Additional specimens examined. Chile. Región V: Valparaíso, Valle de Marga-Marga (coast ranges south-easterly from Valparaíso), Jaffuel & Pirion 3276 (GH). **Región Metropolitana:** Santiago, Quinta Normal de Agricultura, 23 Nov 1960; Camino Rungue a Caleu, 28 Nov 1993, Muñoz Schick 3345 (SGO). **Región VI:** Schlegel 3108 (CONC); Rancagua, Angostura, direkt an der Panamericana nach Rancagua, 11 Dec 2006, Zizka 8026 (CONC, FR, SGO); PN Los Cipresses, El Ranchillo, 12 Dec 2006, Zizka 8027 (CONC, FR); PN Los Cipresses, Las Apas, 12 Dec 2006, Zizka 8034 (CONC, FR); Termas de Cauquenes, Ruta del Acido, am Rio Claro, 200 m flussaufwärts von der Ruta, 12 Dec 2006, Zizka 8045 (FR, SGO); Cachapoal, Termas de Cauquenes, 23 Jan 1927, Behn s.n. (CONC-20623); Cachapoal, Baños de Cauquenes, 3–4 Apr 1931, Looser 2015 (GH); Cachapoal, Baños de Cachantún, Prov. de Colchagua, 21 Jan 1934, Looser 2892 (GH); Cachapoal, Complejo turístico La Leonera, 5 Nov 1989, Muñoz & Morera 2394 (SGO); Cachapoal, Termas de Cauquenes en el cerro, 1 Nov 1952, Pfister s.n. (CONC-13060); Colchagua, Philippi s.n. (B n.v., BM). **Región VII:** Constitución, zwischen Constitución und Putu, 13 Dec 2006, Zizka 8050 (CONC, FR); Zizka 8052 (CONC, FR); Constitución, am Strand in der Nähe einer Zellulosefabrik, 14 Dec 2006, Zizka 8073 (CONC, FR).

Philippi did neither specify a holotype, nor a collector in the protologue of *Puya paniculata*, and specified only that the species is frequent in the Colchagua province ("in prov. Colchagua satis frequens est"). Among the collections held at SGO, Muñoz (1960) identified two specimens collected by Landbeck in 1860 as the

types, SGO-46411 and SGO-46414. However, Smith and Looser (1935) mentioned *Philippi s.n.* (B), collected in Colchagua, as the type, therefore providing an indirect lectotypification.

Puya coerulea var. monteroana (L.B. Sm. & Looser) L.B. Sm. & Looser, Phytologia 19: 287. 1970. *Puya violacea* var. *monteroana* L.B. Sm. & Looser, Revista Univ. (Santiago) 20: 252. 1935. Type: Chile, Colchagua, Cerro Centinela (San Fernando), Oct 1925, G. Montero 26 (holotype: GH).

Plants in flower ca. 1–1.4 m high. Leaf sheath 2–4.7×2.2–3.3 cm; blade 19–48×0.8–1.1 cm. Partial inflorescence basally sterile for 6–6.5 cm, flowers loosely spaced, rachis whitish woolly, glabrescent; floral bracts 0.5–2.5×0.25–0.6 cm, thinly membranous, reaching to the base, rarely to the middle of the sepals; pedicel 9–12 (–19)×1.5–2 mm.

Distribution and Ecology.—Endemic to Chile; distributed in Regions VI and VII (34°–35°S), between 400 and 1200 m.

Conservation.—Vulnerable (Zizka et al., 2009).

Additional specimens examined. Chile. Región VI: PN Los Cipresses, Las Aspas, 12 Dec 2006, Zizka 8030 (CONC, FR); Zizka 8035 (CONC, FR); Cachapoal, Baños de Requínoa, al puente del Requínoa, 21 Jan 1934, Looser 2891 (US); Colchagua, Cerro Centinela (San Fernando), Oct 1925, Montero 26 (GH); Colchagua, Río Claro (Sierra Bellavista), 25 Oct 1969, Zöllner 4524 (CONC); Colchagua, *Philippi s.n.* (HBG-11/1737). **Región VII:** Constitución, zwischen Constitución und Putu, 13 Dec 2006, Zizka 8051 (FR, SGO).

Pourretia violacea Linden, Bot. Zeitung (Berlin) 11: 718. 1853. Type: Description.

Plants in flower 1–2.7 m high. Leaf sheath 3–6.5×1.5–7 cm; blade 11–56×0.4–1.6 cm. Scape red below fertile part. Inflorescence with a red axis; partial inflorescence basally sterile for 4.5–9 cm, with the flowers loosely spaced, whitish woolly, glabrescent; primary bracts 1.4–3×0.4–1.2 cm; floral bracts 0.3–1.2×0.1–0.3 cm, thinly membranous, much shorter than the pedicels; pedicel 10–24×1.5–2 mm, black-violet.

Distribution and ecology.—Endemic to Chile; distributed from Region VI (Termas de Cauquenes, 34° 14' S) to Region VIII (Chillán, 36°38'S), between 100 and 1300 m. Grows in stony areas.

Phenology.—Flowering from December to March.

Conservation.—Vulnerable (Zizka et al., 2009).

Vernacular names.—Chagual chico, Chagualillo, Pilpolle.

Puya venusta Phil., Reise Atacama: 4. 1860; Phil., Anales Univ. Chile 91: 613. 1895. Type: Chile, Región IV: in der Nähe von Coquimbo, without date, *Philippi* 940 (lectotype [see comments below], designated by Smith & Looser, 1935: B; photo of B specimen: G, GH). (Fig. 1)

Pitcairnia venusta (Phil.) Baker, Handb. Bromel.: 123. 1889. Type: Chile, Coquimbo, in der Nähe von Coquimbo, without date, *Philippi* 940 (lectotype, designated by Smith & Looser, 1935: B; photo of B specimen: G, GH).

Pitcairnia sphaerocephala Baker, Handb. Bromel.: 123. 1889. Type: Chile, Region IV: Coquimbo, C. Gaudichaud 55 (holotype: P).

Puya gaudichaudii Mez, Monogr. Phaner. [DC.] 9: 496. 1896. Type: Chile, Region IV: Coquimbo, C. Gaudichaud 56 (holotype: P; photos of holotype: NY, GH).

Puya coquimbensis Mez, Monogr. Phaner. [DC.] 9: 492. 1896. Type: Chile, Region IV: Coquimbo, 1835, C. Gaudichaud 52 (lectotype, designated by Smith & Downs, 1974: B).

Plants caulescent, in flower 1.2–1.8 m high, stems prostrate, branched, over 40 cm long. Leaves numerous, in a dense rosette of approx. 60 cm in diameter, arching; sheath (1.3–)3–9×(1.3–)3.2–9 cm, ovate to orbicular, clearly distinct from blade, below dark castaneous and lepidote in upper third, straw coloured and glabrous towards base; blade 10–46×1–3.5 cm, greyish-green, densely lepidote on both surfaces, spinose, the spines 3–5 mm long, brown to reddish, 0.1–0.7 cm apart at leaf base, 2 cm apart towards apex. Scape 56–150×1–1.5 cm, red, hairy with stellate hairs when young, glabrescent; scape bracts triangular to ovate, acute to acuminate, 3.5–6×1.4–3.5 cm, violet to brown, lepidote, chartaceous to membranous, inconspicuously nerved, serrate. Inflorescence simple and a raceme or compound of racemose partial inflorescences, these ± ovate in outline, 7–14 cm long, the axis lepidote, basally sterile for 3–7 cm, flowers very densely spaced above; primary bracts ovate, 3.7–7.2×1.5–3.7 cm, violet to brown when dried, chartaceous to membranous, inconspicuously nerved, ± serrate;

floral bracts imbricate, elliptical to obovate, acute to acuminate, 2.2–4.3(–7.2)×0.8–2 (–3.5) cm, ± exceeding the sepals, violet, membranous, inconspicuously nerved, margin±serrate; pedicel 5–15×2 mm. Flowers 3–4.5 cm long; sepals lanceolate, apex rounded, sometimes with a mucro, 1.2–2.3×0.2–0.7 cm, light brown, often tinged with violet, membranous to coriaceous, nerved, entire; petals elliptical to obovate, rounded to rarely acute, 2.3–3.6×0.5–1 cm, dark blue to dark violet, black when dried, with 2 appendages at base; stamens 6, filaments 2.2–3 cm long, anthers 3.5–8.5×1–1.5 mm, pollen yellow to orange; ovary 5–7×3–4 mm, style 1.9–2.9 cm long, stigmas 3–8 mm long. Fruit 1–2×1.5–2 cm; seeds 2.7–4.3×1.7–2.2 mm, ± triangular in outline, with membranous wing.

Distribution and ecology.—Endemic to Chile; distributed from Region IV (Coquimbo, 29°57'S) to Region V (Isleto "Cerro de la Cruz" de Zapallar, 32°34'S), between 5 and 250(–750) m; grows in sandy or rocky areas, forming dense stands.

Phenology.—Flowering between August and December.

Conservation.—Vulnerable (Zizka et al., 2009)

Vernacular names.—Chagual chico, Chagualillo.

Additional specimens examined. Chile. Región IV:

Philippi (1860: 4) in his “Reise durch die Wüste Atacama” published the name *Puya venusta* including a short diagnosis: “An ein paar Stellen fand ich auf dem Felsen eine prachtvolle Pourretia (oder *Puya*, *P. venusta* Ph.), Sie hat graue Blätter, einen 3–4 Fuss hohen, hochkermesinrothen Blüthenstiel, graue Brakteen, und lavendelblaue Blumen mit safrangelben Staubgefäßsen [At some places on the rock I found a splendid Pourretia (or *Puya*, *P. venusta* Ph.), that has grey leaves, a 3–4 feet high, strongly carmine peduncle, grey bracts, and lavender flowers with saffron-yellow anthers].” This publication is valid following the ICBN (McNeill et al., 2007), Art. 34.1(a), since *Philippi* expressed his doubts about the taxonomic identity (*Pourretia* or *Puya*), but accepted the species. Hence Baker (1889), when describing *Pitcairnia venusta*, referring to *Puya venusta* Phil. inedit. as a “basionym” produced a new combination. *Philippi*’s description of *Puya venusta* (*Philippi* 1895) was obviously intended

by him as the original publication of that species. Therein he specified the vicinities of Coquimbo as the type locality (“jam. 1860 in itinere atacamensi indicata, sed non descripta. Habitat prope Coquimbo”). Later, Smith and Looser (1935) cited the Berlin specimen of *Philippi* 940 – a specimen without collection date – as the holotype of that species, which is here considered an indirect lectotypification. Although, Muñoz (1960) identified among *Philippi*’s collections held at SGO the specimen *Philippi s.n.* (SGO-46405, collected near Coquimbo in 1853) as the type of *P. venusta*, there is no reason to reject Smith and Looser’s indirect lectotypification.

Puya venusta is well circumscribed and is easily recognized by its blue flowers that are apically congested in the lateral inflorescences. Putative hybrids between *P. venusta* and *P. chilensis* have been observed in the region of Zapallar (Zizka et al., 2009).

Acknowledgments

We thank the Chilean authorities, especially the Corporación Nacional Forestal (CONAF) for various support and permission to collect plant material. We are grateful to the directors of herbaria B, BM, CONC, E, FR, FRP, G, GH, HAL, HBG, MO, NY, SGO, US, and WU for providing material. Special thanks are due to the herbaria and staff of CONC and SGO for their support. We thank Chilean botanists, conservationists, and friends for important informations about collections, bromeliad habitats, companionship, and support during field trips, especially Otto Zoellner, Roberto R. Rodriguez, Melica Muñoz-Schick, Andrés Moreira-Muñoz, and Carlos Trabold. We also thank Claudia Hornung and an anonymous reviewer for helpful comments. The drawings were done by Anna Sarah Becker. The studies were financially supported by the Deutsche Forschungsgemeinschaft (DFG ZI 557/6, 7–1, SCHU 2426/1-1). The authors also acknowledge funding from the research funding program “LOEWE – Landes-Offensive zur Entwicklung Wissenschaftlich-ökonomischer Exzellenz” of the Hesse’s Ministry of Higher Education, Research, and the Arts (Biodiversity and Climate Research Center, BiK-F).
